<b>(54) Title:</b> MICROCONTROLLER INSTRUCTION SET  <b>(57) Abstract</b>  A microcontroller apparatus is provided with an instruction set for manipulating the behavior of the microcontroller. The apparatus and system is provided that enables a linearized address space that makes modular emulation possible. Direct or indirect addressing is possible through register files or data memory. Special function registers, including the Program Counter (PC) and Working Register (W), are mapped in the data memory. An orthogonal (symmetrical) instruction set makes possible any operation on any register using any addressing mode. Consequently, two file registers to be used in some two operand instructions. This allows data to be moved directly between two registers without going through the W register. Thus increasing performance and decreasing program memory usage.

**MICROCONTROLLER INSTRUCTION SET**

This application is related to the following applications: U.S. Application Serial Nos. 08/887,876 for "FORCE PAGE ZERO PAGING SCHEME FOR  
5 MICROCONTROLLERS USING DATA ACCESS MEMORY" on 07/03/98 by Randy L. Yach, et al. (MTI-1225); 08/937,682 for "ROBUST MULTIPLE WORK INSTRUCTION AND METHOD THEREFOR" on 08/29/98 by Rodney J. Drake, et al. (MTI-1254); 08/946,426 for "PROCESSOR ARCHITECTURE SCHEME FOR IMPLEMENTING VARIOUS ADDRESSING MODES AND METHOD  
10 THEREFOR" on 10/07/97 by Sumit Mitra, et al. (MTI-1265); 08/958,940 for "A SYSTEM FOR ALLOWING A TWO WORD INSTRUCTION TO BE EXECUTED IN A SINGLE CYCLE AND METHOD THEREFOR" on 10/28/98 by Rodney J. Drake, et al. (MTI-1298); 08/959,405 entitled "PROCESSOR ARCHITECTURE SCHEME HAVING MULTIPLE SOURCE FOR SUPPLYING BANK ADDRESS  
15 VALUES AND METHOD THEREFORE" filed on 10/28/97 by Igor Wojewoda, Sumit Mitra, and Rodney J. Drake (MTI-1299); 08/959,559 for "DATA POINTER FOR OUTPUTTING INDIRECT ADDRESSING MODE ADDRESSES WITHIN A SINGLE CYCLE AND METHOD THEREFOR" on 10/29/98 by Rodney J. Drake, et al. (MTI-1300); 08/958,939 for "PRE-DECODED STACK POINTER WITH POST  
20 INCREMENT/DECREMENT OPERATION" on 10/28/98 by Allen, et al. (MTI-1306); and 08/959,942 for "PROCESSOR ARCHITECTURE SCHEME AND INSTRUCTION SET FOR MAXIMIZING AVAILABLE OPCODES AND FOR IMPLEMENTING VARIOUS ADDRESSING MODES" on 10/29/97 by Triece, et al. (MTI-1314) which are hereby incorporated herein by reference for all purposes.

## BACKGROUND OF THE INVENTION

### FIELD OF THE INVENTION

The present invention relates to microcontrollers and, more specifically, the present invention relates to opcode instructions that are gathered into an instruction set  
5 which are used to manipulate the behavior of the microcontroller.

### DESCRIPTION OF THE RELATED TECHNOLOGY

Microcontroller units (MCU) have been used in the manufacturing and electrical industries for many years. Figure 1 shows a typical core memory bus arrangement for mid-range MCU devices. In many cases, microcontrollers utilize reduced instruction  
10 set computing (RISC) microprocessors. The high performance of some of these devices can be attributed to a number of architectural features commonly found in RISC microprocessors. These features include:

- ☐ Harvard architecture
- ☐ Long Word Instructions
- 15 ☐ Single Word Instructions
- ☐ Single Cycle Instructions
- ☐ Instruction Pipelining
- ☐ Reduced Instruction Set
- ☐ Register File Architecture
- 20 ☐ Orthogonal (Symmetric) Instructions

#### Harvard Architecture:

As shown in Figure 1, the Harvard architecture has the program memory 26 and data memory 22 as separate memories and are accessed by the CPU 24 from separate  
25 buses. This improves bandwidth over traditional von Neumann architecture (shown in Figure 3) in which program and data are fetched by the CPU 34 from the same memory 36 using the same bus. To execute an instruction, a von Neumann machine must make one or more (generally more) accesses across the 8-bit bus to fetch the instruction. Then data may need to be fetched, operated on, and possibly written. As can be seen  
30 from this description, that bus can be extremely congested.

In contrast to the von Neumann machine, under the Harvard architecture, all 14 bits of the instruction are fetched in a single instruction cycle. Thus, under the Harvard architecture, while the program memory is being accessed, the data memory is on an independent bus and can be read and written. These separated buses allow one  
5 instruction to execute while the next instruction is being fetched.

#### Long Word Instructions:

Long word instructions have a wider (more bits) instruction bus than the 8-bit Data Memory Bus. This is possible because the two buses are separate. This further allows instructions to be sized differently than the 8-bit wide data word which allows a  
10 more efficient use of the program memory, since the program memory width is optimized to the architectural requirements.

#### Single Word Instructions:

Single Word instruction opcodes are 14-bits wide making it possible to have all single word instructions. A 14-bit wide program memory access bus fetches a 14-bit  
15 instruction in a single cycle. With single word instructions, the number of words of program memory locations equals the number of instructions for the device. This means that all locations are valid instructions. Typically in the von Neumann architecture (shown in Figure 3), most instructions are multi-byte. In general however, a device with 4-KBytes of program memory would allow approximately 2K of instructions.  
20 This 2:1 ratio is generalized and dependent on the application code. Since each instruction may take multiple bytes, there is no assurance that each location is a valid instruction.

#### Instruction Pipeline:

The instruction pipeline is a two-stage pipeline which overlaps the fetch and  
25 execution of instructions. The fetch of the instruction takes one machine cycle (TCY), while the execution takes another TCY. However, due to the overlap of the fetch of current instruction and execution of previous instruction, an instruction is fetched and another instruction is executed every single TCY.

Single Cycle Instructions:

With the Program Memory bus being 14-bits wide, the entire instruction is fetched in a single TCY. The instruction contains all the information required and is executed in a single cycle. There may be a one-cycle delay in execution if the result of the instruction modified the contents of the Program Counter. This requires that the pipeline be flushed and a new instruction fetched.

Reduced Instruction Set:

When an instruction set is well designed and highly orthogonal (symmetric), fewer instructions are required to perform all needed tasks. With fewer instructions, the whole set can be more rapidly learned.

Register File Architecture:

The register files/data memory can be directly or indirectly addressed. All special function registers, including the program counter, are mapped in the data memory.

Orthogonal (Symmetric) Instructions:

Orthogonal instructions make it possible to carry out any operation on any register using any addressing mode. This symmetrical nature and lack of "special instructions" make programming simple yet efficient. In addition, the learning curve is reduced significantly. The mid-range instruction set uses only two non-register oriented instructions, which are used for two of the cores features. One is the SLEEP instruction that places the device into the lowest power use mode. The other is the CLRWDT instruction which verifies the chip is operating properly by preventing the on-chip Watchdog Timer (WDT) from overflowing and resetting the device.

Clocking Scheme/Instruction Cycle:

The clock input (from OSC1) is internally divided by four to generate four non-overlapping quadrature clocks, namely Q1, Q2, Q3, and Q4. Internally, the program counter (PC) is incremented every Q1, and the instruction is fetched from the program memory and latched into the instruction register in Q4. The instruction is decoded and

executed during the following Q1 through Q4. The clocks and instruction execution flow are illustrated in Figures 4 and 5.

Instruction Flow/Pipelining:

An "Instruction Cycle" consists of four Q cycles (Q1, Q2, Q3, and Q4) as shown in Figures 4 that comprise the TCY as shown in Figures 4 and 5. Note that in Figure 5, all instructions are performed in a single cycle, except for any program branches. Program branches take two cycles because the fetch instruction is "flushed" from the pipeline while the new instruction is being fetched and then executed.

Fetch takes one instruction cycle while decode and execute takes another instruction cycle. However, due to Pipelining, each instruction effectively executes in one cycle. If an instruction causes the program counter to change (e.g. GOTO) then an extra cycle is required to complete the instruction (Figure 5). The instruction **fetch** begins with the program counter incrementing in Q1. In the **execution** cycle, the fetched instruction is latched into the "Instruction Register (IR)" in cycle Q1. This instruction is then decoded and executed during the Q2, Q3, and Q4 cycles. Data memory is read during Q2 (operand read) and written during Q4 (destination write). Figure 5 shows the operation of the two-stage pipeline for the instruction sequence shown. At time TCY0, the first instruction is fetched from program memory. During TCY1, the first instruction executes while the second instruction is fetched. During TCY2, the second instruction executes while the third instruction is fetched. During TCY3, the fourth instruction is fetched while the third instruction (CALL SUB\_1) is executed. When the third instruction completes execution, the CPU forces the address of instruction four onto the Stack and then changes the Program Counter (PC) to the address of SUB\_1. This means that the instruction that was fetched during TCY3 needs to be "flushed" from the pipeline. During TCY4, instruction four is flushed (executed as a NOP) and the instruction at address SUB\_1 is fetched. Finally during TCY5, instruction five is executed and the instruction at address SUB\_1 + 1 is fetched.

While the prior art microcontrollers were useful, the various modules could not be emulated. Moreover, the type of microcontroller as described in Figure 1 could not linearize the address space. Finally, the prior art microcontrollers are susceptible to compiler-error problems. What is needed is an apparatus, method, and system for a  
5 microcontroller that is capable of linearizing the address space in order to enable modular emulation. There is also a need in the art for reducing compiler errors.

### SUMMARY OF THE INVENTION

The present invention overcomes the above-identified problems as well as other shortcomings and deficiencies of existing technologies by providing a microcontroller  
10 instruction set that eliminates many of the compiler errors experienced in the prior art. Moreover, an apparatus and system is provided that enables a linearized address space that makes modular emulation possible.

The present invention can directly or indirectly address its register files or data memory. All special function registers, including the Program Counter (PC) and  
15 Working Register (W), are mapped in the data memory. The present invention has an orthogonal (symmetrical) instruction set that makes it possible to carry out any operation on any register using any addressing mode. This symmetrical nature and lack of 'special optimal situations' make programming with the present invention simple yet efficient. In addition, the learning curve for writing software applications is reduced  
20 significantly. One of the present invention's enhancements over the prior art allows two file registers to be used in some two operand instructions. This allows data to be moved directly between two registers without going through the W register. Thus increasing performance and decreasing program memory usage.

The preferred embodiment of the present invention includes an ALU/W register, a  
25 PLA, an 8-bit multiplier, a program counter (PC) with stack, a table latch/table pointer, a ROM latch/IR latch, FSRs, interrupt vectoring circuitry, and most common status registers. Unlike the prior art, the design of the present invention obviates the need for a

timer in a separate module, all reset generation circuitry (WDT, POR, BOR, etc.), interrupt flags, enable flags, INTCON registers, RCON registers, configuration bits, device ID word, ID locations, and clock drivers.

Additional embodiments will be clear to those skilled in the art upon reference to  
5 the detailed description and accompanying drawings.

### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The present invention is an apparatus, method and system for providing, in several embodiments, a microcontroller instruction set and microcontroller architecture that includes a linearized address space that enables modular emulation.

5       The architecture of the apparatus of the preferred embodiment of the present invention modifies the prior art Harvard architecture in that the data path is 8-bit and the instruction length is 16-bit with a four-phase internal clocking scheme. Moreover, the preferred embodiment has a linearized memory addressing scheme that eliminates the need for paging and banking. The memory addressing scheme of the present  
10       invention allows for program memory addressability up to 2M bytes. Emulation of modules is also supported by the present invention.

      The present invention overcomes the above-identified problems as well as other shortcomings and deficiencies of existing technologies by providing a microcontroller instruction set that eliminates many of the compiler errors experienced in the prior art.  
15       Moreover, an apparatus and system is provided that enables a linearized address space that makes modular emulation possible.

      The present invention can directly or indirectly address its register files or data memory. All special function registers, including the Program Counter (PC) and Working Register (W), are mapped in the data memory. The present invention has an  
20       orthogonal (symmetrical) instruction set that makes it possible to carry out any operation on any register using any addressing mode. This symmetrical nature and lack of 'special optimal situations' make programming with the present invention simple yet efficient. In addition, the learning curve is reduced significantly. One of the present invention family architectural enhancements from the prior art allows two file registers  
25       to be used in some two operand instructions. This allows data to be moved directly between two registers without going through the W register. Thus increasing performance and decreasing program memory usage. Figure 6 shows a block diagram for the microcontroller core of the present invention.

The microcontroller core 100 of the present invention is illustrated in Figure 6. By convention, connecting signal lines in Figure 6 can contain a slash with an adjacent number indicating the bandwidth (in bits) of the signal line. Referring to the upper right corner of Figure 6, we find a data memory 104 that is used for storing and transferring data to and from a central processing unit (described below). The data memory 104 is composed of a plurality of address locations. In the preferred embodiment of the present invention, the data memory 104 is a linearized 4K memory which is divided into a plurality of sixteen pages or banks. Typically, each bank has 256 address locations. In the preferred embodiment, one of the plurality of banks is a dedicated to general and specific purpose registers, in this case the topmost bank, bank 0.

A selection circuit 108 is coupled to the data memory 104 through an address latch 102. The selection circuit 108 is used for selecting one of the plurality of sources that supply the bank address values in the data memory 104

The preferred embodiment of the present invention includes an ALU 140 with working (W) register 136, a PLA, an 8-bit multiplier, a program counter (PC) 168 with stack 170, a table latch 124, table pointer 148, a ROM latch 152 with IR latch 126, FSRs 120, 121, 122, interrupt vectoring circuitry, and most common status registers. Unlike the prior art, the design of the present invention obviates the need for a timer in a separate module, all reset generation circuitry (WDT, POR, BOR, etc.), interrupt flags, enable flags, INTCON registers, RCON registers, configuration bits, device ID word, ID locations, and clock drivers.

#### I/O List:

A generous list of input/output (I/O) commands are available with the present invention, the I/O list is shown in Table 1.

Table 1 I/O List

Name	Count I/O	Normal Operation	Operation Test Module	Program Module	Emulation Module
addr<21:0>	22/O	Program Memory address			
nqbank<3:0>	4/O	Active low RAM bank selection			
d<15:0>	16/I	Program memory data			
db<7:0>	8/ I/O	Data bus			
forcest	1/I		Force external instruction test mode		
irp<7:0>	8/O	Peripheral Address			
irp9	1/O	Instruction register bit 9			
ncodeprt	1/I	Active low code protect			
neprtim	1/I	Active low end of EPROM write			
nhalt	1/I				Active low halt
nintake	1/I	Active low interrupt acknowledge early and wake up from sleep			
np<7:0>	8/O	Table latch data			
npcmux	1/O	Active low PC multiplex			
npchold	1/O	Active low PC hold			
nprrchg	1/I	Active low port change interrupt			
nq4clrwdt	1/O	Active low clear wdt			
nq4sleep	1/O	Active low sleep

### Clocking Scheme/Instruction Cycle

The clock input (from OSC1) is internally divided by four to generate four non-overlapping quadrature clocks, namely Q1, Q2, Q3, and Q4 as shown in Figure 7. Internally, the program counter (PC) is incremented every Q1, and the instruction is  
 5 fetched from the program memory and latched into the instruction register using Q4. The instruction is decoded and executed during the following Q1 through Q4. The PLA decoding is done during Q1. During the Q2 and Q3 cycle, the operand is read from memory or peripherals and the ALU performs the computation. During Q4 the results are written to the destination location. The clocks and instruction execution  
 10 flow are shown in Figure 8.

### Q Cycle Activity

Each instruction cycle (TCY) is comprised of four Q cycles (Q1-Q4) as shown in Figure 7. The Q cycle is the same as the device oscillator cycle (TOSC). The Q cycles provide the timing/designation for the Decode, Read, Process Data, Write etc., of  
 15 each instruction cycle. The following diagram (Figure 7) shows the relationship of the Q cycles to the instruction cycle. The four Q cycles that make up an execution instruction cycle (TCY) can be generalized as:

- Q1: Instruction Decode Cycle or forced NOP
- Q2: Instruction Read Cycle or NOP
- Q3: Process the Data
- Q4: Instruction Write Cycle or NOP

Each instruction will show the detailed Q cycle operation for the instruction.

### Instruction Flow/Pipelining

An "Instruction Cycle" consists of four Q cycles (Q1, Q2, Q3, and Q4). The instruction fetch and execute are pipelined such that fetch takes one instruction cycle while decode and execute takes another instruction cycle. However, due to the pipelining, each instruction effectively executes in one cycle. There are 4 types of instruction flows. First is a normal 1-word 1 cycle pipelined instruction. These instructions will take one effective cycle to execute as shown in Figure 9. Second is a 1 word 2 cycle pipeline flush instruction. These instructions include the relative branches, relative call, skips and returns. When an instruction changes the PC, the pipelined fetch is discarded. This makes the instruction take two effective cycles to execute as shown in Figure 10. Third are the table operation instructions. These instructions will suspend the fetching to insert and read or write cycle to the program memory. The instruction fetched while executing the table operation is saved for 1 cycle and executed in the cycle immediately after the table operation as shown in Figure 11. Fourth are new two word instructions. These instructions include MOVFF and MOVLf. In these instructions, the fetch after the instruction contains the remainder of the addresses. For a MOVFF instruction during execution of the first word, the machine will execute a read of the source register. During execution of the second word, the source address is obtained, and then the instruction will complete the move as shown in Figure 12. The MOVLf is similar although it moves 2 literal values into FSRnH and FSRnL in 2 cycles as shown in Figure 13. Fifth, is the two word instructions for CALL and GOTO. In these instructions, the fetch after the instruction contains the remainder of the jump or call destination addresses. Normally, these instructions would require 3 cycles to execute, 2 for fetching the 2 instruction words and 1 for the subsequent pipeline flush. However, by providing a high-speed path on the second fetch, the PC can be updated with the complete value in the first cycle of

instruction execution, resulting in a 2 cycle instruction as shown in Figure 14. Sixth, is the interrupt recognition execution. Instruction cycles during interrupts are discussed in the interrupts section below.

### The ALU

5       The present invention contains an 8-bit Arithmetic and Logic Unit (ALU)142 and working register 136 as shown in Figure 6. The ALU 142 is a general purpose arithmetic unit. It performs arithmetic and Boolean functions between data in the working register and any register file. The ALU 142 is 8-bits wide and capable of addition, subtraction, shift, and logical operations. Unless otherwise mentioned,  
10       arithmetic operations are two's complement in nature. The working (W) register 136 is an 8-bit working register used for ALU 140 operations. The W register 136 is addressable and can be directly written or read. The ALU 140 is capable of carrying out arithmetic or logical operations on two operands or a single operand. All single operand instructions operate either on the W register 136 or the given file register. For  
15       two operand instructions, one of the operands is the W register 136 and the other one is either a file register or an 8-bit immediate constant, or an equivalent storage medium.

      Depending on the instruction executed, the ALU 140 may affect the values of the Carry (C), Digit Carry (DC), Zero (Z), Overflow (OV), and Negative (N) bits in the STATUS register (discussed below). The C and DC bits operate as a borrow and digit  
20       borrow out bit, respectively, in subtraction.

      The preferred embodiment of the present invention includes an 8 x 8 hardware multiplier 134 included in the ALU 142 of the device as shown in Figure 6. By making the multiply a hardware operation, the operation completes in a single instruction cycle. This hardware operation is an unsigned multiply that gives a 16-bit result. The result is  
25       stored into the 16-bit product register (PRODH:PRODL). The multiplier does not affect any flags in the STATUS register.

### Status Registers

The STATUS register contains the status bits of the ALU 140. The status register is shown in Figure 15. In the preferred embodiment of the present invention, bit 7-5 are unimplemented and are read as '0'.

5 bit 4 is "N", the Negative bit. This bit is used for signed arithmetic (2's complement). It indicates whether the result was negative, (ALU MSb = 1), 1 = Result was negative, 0 = Result was positive.

bit 3 is the "OV" Overflow bit. This bit is used for signed arithmetic (2's complement). It indicates an overflow of the 7-bit magnitude, which causes the sign bit (bit 7) to change state. For this bit, 1 = Overflow occurred for signed arithmetic, (in this  
10 arithmetic operation), and 0 = No overflow occurred.

bit 2 is the "Z" Zero bit. For this bit, 1 = The result of an arithmetic or logic operation is zero, and 0 = The results of an arithmetic or logic operation is non-zero.

bit 1 is the "DC" Digit carry/borrow bit. For this bit, 1 = A carry-out from the  
15 4th low order bit of the result occurred, and 0 = No carry-out from the 4th low order bit of the result

It should be noted that, for borrow, the polarity is reversed.

bit 0 is the "C" carry/borrow bit. For this bit, 1 = A carry-out from the most significant bit of the result occurred, and 0 = No carry-out from the most significant bit  
20 of the result. As with bit 1, for borrow the polarity is reversed.

The C and DC bits operate as a borrow and digit borrow bit, respectively, in subtraction. Carry is ALU bit 7 carry out. Digit Carry is ALU bit 3 carry out. Zero is true if ALU result bit <7:0> is '0'. N is ALU result bit 7. The overflow bit will be set if the 2's complement result exceeds +127 or is less than -128. Overflow is ALU bit 6  
25 carry out XOR ALU bit 7 carry out. As with all the other registers, the STATUS register can be the destination for any instruction. If the STATUS register is the write destination for an instruction that affects any of the status bits, then the write to the status bits is disabled. The bits are set or cleared according to the ALU results and the

instruction specification. Therefore, the result of an instruction with the STATUS register as destination may be different than intended.

For example, the CLRF REG instruction normally writes the register to 0 and sets the Z bit. The CLRF STATUS instruction will disable the write to the N, OV, DC and C bits and set the Z bit. This leaves the STATUS register as 000u u1uu. It is recommended, therefore, that only the BCF, BSF, SWAPF and MOVWF instructions be used to alter the STATUS register because these instructions do not affect any status bit. To see how other instructions affect the status bits, see the "Instruction Set Summary."

#### 10        Program Counter Module

The program counter (PC)168 (see Figure 6) is modified to allow expansion up to a maximum of 21 bits. This is done by adding a 5-bit wide PCLATU register that operates similarly to the PCLATH register. The PC 168 is also modified to address bytes rather than words in the program memory. To implement this, there is a byte addressing bit at the LSb of the PC 168 that is always 0. The LSb bit of the PCL is readable but not writeable. Should the user attempt to write a '1' into the LSb, the result will be a '0'. To allow hidden test EPROM, there is a hidden 22nd bit (bit21) of PC 168 (see Figure 16). This PC bit is normally 0. When entering test mode or programming mode, this bit is set and the instructions will be fetched from the test area. Once this bit is set, it cannot be cleared by program execution, the device must be reset.

The Program Counter (PC) 168 is up to a 21-bit register as shown in Figure 16. PCL 184, the low byte of the PC 168, is mapped in the data memory 104 (see Figure 6). PCL 184 is readable and writable just as is any other register. PCH 182 and PCU 180 are the high bytes of the PC and are not directly addressable. Since PCH 182 and PCU 184 are not mapped in data or program memory 160, registers PCLATH 178 (PC high latch) and PCLATU 176 (PC upper latch) are used as holding latches for the high bytes of the PC 168.

PCLATH 178 and PCLATU 176 are mapped into data memory 104. The user can read and write PCH 182 through PCLATH 178 and PCU 180 through PCLATU 176. The PC 168 is word incremented by 2 after each instruction fetch during Q1 unless:

- 5       • Modified by a GOTO, CALL, RETURN, RETLW, RETFIE, or Branch instruction.
- Modified by an interrupt response.
- Due to destination write to PCL 168 by an instruction.

- 10       “Skips” are equivalent to a forced NOP cycle at the skipped address. Figures 16 and 17 show the operation of the program counter for various situations.

Referring to Figure 16, the operations of the PC 168, PCLATH 178, and PCLATU 176 for different instructions are as follows:

a. Read instructions on PCL:

- 15       For any instruction that reads PCL 184. All byte instructions with d=0; MOVFF PCL, X; CPFSEQ; CPFSGT; CPFSLT; MULWF; TSTFSZ then PCL to data bus then to ALU or to the destination. Finally, PCH to PCLATH and PCU to PCLATU.

20       b. Write instructions on PCL:

Any instruction that writes to PCL 184. For example, MOVWF; CLRF; SETF, then write 8-bit data to the data bus 174 and then to PCL 184. Also, PCLATH to PCH, and PCLATU to PCU.

c. Read-Modify-Write instructions on PCL:

- 25       Any instruction that does a read-write-modify operation on PCL. All byte instructions with d=1; Bit Instructions; NEGF. Read: PCL to data bus to ALU. Write: write the 8-bit result to data bus and to PCL; then PCLATH to PCH; and finally PCLATU to PCU.

The read-modify-write only affects the PCL 184 with the result. PCH 182 and PCU 180 are loaded with the value in the PCLATH 178 and PCLATU 176 respectively. For example, for the instruction "ADDWF", PCL 184 will result in the following jump. If PC = 0003F0h, W = 30h, PCLATH = 05h and PCLATU = 1h before the instruction, PC = 010520h after the instruction. To accomplish a true 20-bit computed jump, the user needs to compute the 20-bit destination address, write to PCLATH 178 and PCLATU 176, and then write the low value to PCL 168.

10                    d. RETURN instruction:

Stack<MRU> to PC<20:0> Using Figure 17, the operation of the PC 168 , PCLATH 178, and PCLATU 176 for the GOTO and the CALL instructions is as follows:

15                    e. CALL, GOTO instructions:

A destination address is provided in the 2-word instruction (opcode). The first Word Opcode<6:0> to PCL<7:1>. The first Word Opcode<7> to PCLATH<0> and to PCH<0>. The second Word Opcode<6:0> to PCLATH<7:1> and PCH <7:1>. The second Word Opcode<11:7> to PCLATU<4:0> and PCU <4:0>.

20

It should be noted that the following PC 168 related operations do not change PCLATH 178 and PCLATU 176:

- a. RETLW, RETURN, and RETFIE instructions.
- b. Interrupt vector is forced onto the PC.
- 25       c. Read-modify-write instructions on PCL (e.g. BSF PCL, 2).

Return Stack Operation

The present invention has a 31 level deep return (or hardware) stack. The depth of the stack was increased over the prior art in order to allow more complex programs. The stack is not part of either the program or data memory space.

The PC 168 is pushed onto the stack when a CALL or RCALL instruction is executed or an interrupt is acknowledged. The PC 168 value is pulled off the stack on a RETURN, RETLW, or a RETFIE instruction. PCLATU 176 and PCLATH 178 are not affected by any of the return instructions.

- 5       The stack operates as a 31 word by 21 bit RAM and a 5-bit stack pointer, with the stack pointer initialized to 00000b after all resets. There is no RAM word associated with stack pointer 000h. This is only a reset value. During a CALL type instruction causing a push onto the stack, the stack pointer is first incremented and the RAM location pointed to by the stack pointer is written with the contents of the PC.
- 10       During a RETURN type instruction causing a pop from the stack, the contents of the RAM location pointed to by the STKPTR is transferred to the PC and then the stack pointer is decremented.

#### Top Of Stack Access

- 15       The top of the stack is readable and writeable. Three register locations, TOSU, TOSH and TOSL address the stack RAM location pointed to by the STKPTR. This allows users to implement a software stack if necessary. After a CALL or RCALL instruction or an interrupt, the software can read the pushed value by reading the TOSU, TOSH and TOSL registers. These values can be placed on a user defined software stack. At return time, the software can replace the TOSU, TOSH and TOSL
- 20       and do a return. It should be noted that the user must disable the global interrupt enable bits during this time to prevent inadvertent stack operations.

#### PUSH and POP instructions

- 25       Since the Top-of-stack (TOS) is readable and writable, the ability to push values onto the stack and pull values off the stack without disturbing normal program execution is a desirable option. To push the current PC value onto the stack, a PUSH instruction can be executed. This will push the current PC value onto the stack; setting the TOS = PC and PC = PC + 2. The ability to pull the TOS value off of the stack and replace it with the value that was previously pushed onto the stack, without disturbing normal execution, is achieved by using the POP instruction. The POP instruction pulls

the TOS value off the stack, but this value is not written to the PC; the previous value pushed onto the stack then becomes the TOS value.

#### Return Stack Pointer (STKPTR)

The STKPTR register contains the return stack pointer value and the overflow and underflow bits. The stack overflow bit (STKOVF) and underflow bit (STKUNF) allow software verification of a stack condition. The STKOVF and STKUNF bits are cleared after a POR reset only.

After the PC is pushed onto the stack 31 times (without popping any values off the stack), the 32nd push over-writes the value from the 31st push and sets the STK-  
OVF bit while the STKPTR remains at 11111b. The 33<sup>rd</sup> push overwrites the 32nd  
push (and so on) while STKPTR remains 11111b.

After the stack is popped enough times to unload the stack, the next pop will return a value of zero to the PC and sets the STKUNF bit while the STKPTR remains at 00000b. The next pop returns zero again (and so on) while STKPTR remains 00000b.  
Note that returning a zero to the PC on an underflow has the effect of vectoring the program to the reset vector where the stack conditions can be verified and appropriate actions can be taken.

The stack pointer can be accessed through the STKPTR register. The user may read and write the stack pointer values. This can be used by RTOS for return stack maintenance. Figure 18 shows the STKPTR register. The value of the stack pointer will be 0 through 31. At reset the stack pointer value will be 0. The stack pointer when pushing will increment and when popping will decrement.

#### Stack Overflow/Underflow Resets

At the user's option, the overflow and underflow can cause a device reset to interrupt the program code. The reset is enabled with a configuration bit, STVRE. When the STVRE bit is disabled, an overflow or underflow will set the appropriate STKOVF or STKUNF bit and not cause a reset. When the STVRE bit is enabled, a over-flow or underflow will set the appropriate STKOVF or STKUNF bit and then cause a device reset very similar in nature to the WDT reset. In either case, the

STKOVF or STKUNF bits are not cleared unless the user software clears them or a POR reset clears them. Figures 18-21 illustrate stack registers. Figures 22-29 illustrate stack operations.

### Program Memory

5       The preferred embodiment of the present invention has up to a 2Megabyte (2M) x 8 user program memory space. The program memory space is primarily to contain instructions for execution, however, data tables may be stored and accessed using the table read and write instructions. Another 2M x 8 test program memory space is available for test ROM, configuration bits, and identification words.

10       The devices have up to a 21-bit program counter capable of addressing the 2M x 8 program memory space. There is also a 22nd PC bit that is hidden during normal operation, and when it is set, it is possible to access configuration bits, device ID and test ROM. This bit can be set in test mode or programming mode, and the device must be reset to clear this bit. User program memory space cannot be accessed with this bit  
15       set. Because the PC must access the instructions in program memory on an even byte boundary, the LSb of the PC is an implied '0' and the PC increments by two for each instruction.

      The reset vector is at 000000h and the high priority interrupt vector is at 000008h and the low priority interrupt vector is at 000018h (see Figure 30).

### 20       Program Memory Organization

      Each location in the program memory has a byte address. In addition, each 2 adjacent bytes have a word address. Figure 31 shows the map of the program memory with byte and word addresses shown. Within the program memory, the instructions must be word aligned. Figure 32 shows the map of the program memory with several  
25       example instructions and the hex codes for those instructions placed into the map. Table operations will work with byte entities. A table block is not required to be word aligned, so a table block can start and end at any byte address. The exception to this is if a table write is being used to program the internal program memory or an external

word wide flash memory. When programming, the write data may need to be aligned to the word width used by the programming method.

### Program Memory Modes

The present invention can operate in one of five possible program memory configurations. The configuration is selected by configuration bits. The possible modes are:

- MP - Microprocessor
- EMC - Extended Microcontroller
- PEMC - Protected Extended Microcontroller
- 10 • MC - Microcontroller
- PMC - Protected Microcontroller

The microcontroller and protected microcontroller modes only allow internal execution. Any access beyond the program memory reads all zeros. The protected micro-controller mode also enables the code protection feature. Microcontroller is the default mode of an un-programmed device.

The extended microcontroller mode accesses both the internal program memory as well as external program memory. Execution automatically switches between internal and external memory. The 21-bits of address allow a program memory range of 2M-bytes. The protected extended microcontroller mode will code protect the internal program memory by preventing table reads/writes to the internal memory while still allowing execution and table reads/writes of the external program memory.

The microprocessor mode only accesses the external program memory. The on-chip program memory is ignored. The 21-bits of address allow a program memory range of 2M-bytes.

Test memory and configuration bits are readable during normal operation of the device by using the TBLRD instruction. These areas are only modifiable using the TBLWT instruction if the LWRT bit in the RCON register is set or the device is in test and programming mode.

30 These areas can only be executed from in test and programming mode.

The extended microcontroller mode and microprocessor modes are available only on devices which have the external memory bus defined as part of the I/O pins. Table 2 lists which modes can access internal and external memory. Figure 33 illustrates the device memory map in the different program modes.

**Table 2 Device Mode Memory Access**

Operating Mode	Internal Program Memory	External Program Memory
Microprocessor	No Access	Execution / TBLRD / TBLWT
Extended Microcontroller	Execution / TBLRD / TBLWT	Execution / TBLRD / TBLWT
Protected Extended Microcontroller	Execution	Execution / TBLRD / TBLWT
Microcontroller	Execution / TBLRD / TBLWT	No Access
Protected Microcontroller	Execution / TBLRD	No Access

#### External Program Memory Interface

When either microprocessor or extended microcontroller mode is selected, up to four ports are configured as the system bus. Two ports and part of a third are the multiplexed address/data bus and part of one other port is used for the control signals. External components are needed to demultiplex the address and data. The external memory interface can run in 8-bit data mode or 16-bit data mode. Addresses on the external memory interface are byte addresses always.

Figures 36 and 37 describe the external memory connections for 16-bit and 8-bit data respectively. The external program memory bus shares I/O port functions on the pins. Figure 38 lists a typical mapping of external bus functions on I/O pin functions.

In extended microcontroller mode, when the device is executing out of internal memory, the control signals will NOT be active. They will go to a state where the AD<15:0>, A<19:0> are tri-state; the OE, WRH, WRL, UB and LB signals are '1'; UBA0 and ALE is '0'.

5                    16-Bit External Interface

If the external interface is 16-bit, the instructions will be fetched as 16-bit words. The OE output enable signal will enable both bytes of program memory at once to output a 16-bit word. The least significant bit of the address, BA0, need not be connected to the memory devices.

10                  An external table read is logically performed one byte at a time, although the memory will read a 16-bit word externally. The least significant bit of the address will internally select between high and low bytes (LSb = 0 to lower byte, LSb = 1 to upper byte). The external address in microprocessor and extended microcontroller modes is 21-bits wide; this allows addressing of up to 2M-bytes.

15                  An external table write on a 16-bit bus is logically performed one byte at a time. The actual write will depend on the type of external device connected and the WM<1:0> bits in the MEMCON register, shown in Figure 34. The Table Operations section details the actual write cycles.

8-Bit External Interface

20                  If the external interface is 8-bit, the instructions will be fetched as 2 8-bit bytes. The two bytes are fetched within one instruction cycle. The least significant bit of the address must be connected to the memory devices. The OE output enable signal and BA0=1 will enable the most significant byte of the instruction to read from program memory for the Q3 portion of the cycle, then BA0 will change to 0 and the least significant byte will be read for the Q4 portion of the cycle; to form the 16-bit instruction word.

25

An external table read is also performed one byte at a time. An external table write is performed one byte at a time. The WRL is active on every external write.

When 8-bit interface is selected, the WRH, UB and UL lines are not used and the pins revert to I/O port functions. A configuration bit selects the 8-bit mode of the external interface.

#### External Wait Cycles

5       The external memory interface supports wait cycles. The external memory wait cycles only apply to the table read and table write operations over the external bus. Since the device execution is tied to instruction fetches, there is no sense to execute faster than the fetch rate. So if the program fetches need to be slowed, the processor speed must be slowed with a different Tcy time.

10       The WAIT<1:0> bits in the MEMCON register will select 0,1,2 or 3 extra Tcy cycles per memory fetch cycle. The wait cycles will be effective for table reads and writes on a 16-bit interface. On an 8-bit interface, for table reads and writes, the wait will only occur on the Q4.

15       The default setting of the wait on power up is to assert a wait of the maximum of the 3Tcy cycles. This insures that slow memories will work in microprocessor mode immediately after reset. A configuration bit, called WAIT, will enable or disable the wait states. Figure 39 illustrates the 16-bit interface and Figure 40 illustrates the 8-bit, in both cases showing program memory instruction fetches with no waits and table reads with wait states.

#### 20       External Bus Signal Disables

25       To allow flexibility in the utilization of the pins committed to the external bus, several disables are provided in configuration bits. Also, to disable the entire external bus, as might be done while in extended microcontroller mode and allowing a DMA function, the EBDIS bit in the MEM-CON, shown in Figure 35, register. This disable will allow the user to tri-state the entire external bus inter-face. This will allow DMA operations as well as direct control of external devices by program control through the I/O pin functions.

In emulator systems, the -ME devices must have inputs to represent the bus disable configuration bits to allow the I/O port functions to detect the status of the pins

as external interface. The -ME device also has a special input pin that indicates if the emulator system is in the microprocessor or extended microcontroller mode.

### Data Memory

The data memory and general purpose RAM size can be extended to 4096 bytes  
5 in the present invention. The data memory address is 12-bits wide. The data memory is partitioned into 16 banks of 256 bytes which contain the General Purpose Registers (GPRs) and Special Function Registers (SFRs).

The GPR's are mechanized into a byte wide RAM array of the size of the combined GPR registers. The SFR's are typically distributed among the peripherals  
10 whose functions they control.

The bank is selected by the bank select register (BSR<3:0>). The BSR register can potentially access more than 16 banks, however the direct long addressing mode is limited to 12-bit addresses or 16 banks. The BSR is limited accordingly.

Device instructions can read, modify and write a particular location in one  
15 instruction cycle. There is only one address generation per cycle, so it is not possible to read one location and modify/write another in a single cycle. Figure 42 shows an example data memory map.

### General Purpose Registers

In all PIC devices, all data RAM is available for use as registers by all  
20 instructions. Most banks of data memory only contain GPR memory. There must be GPR memory included in bank 0 on all devices.

The absolute minimum for the number of GPRs in bank 0 is 128. This GPR area, called the Access RAM, is essential for allowing programmers to have a data structure that is accessible regardless of the setting of the BSR.

### Special Function Registers

25 SFR are special registers, typically used for device and peripheral control and status functions. They are accessible by all instructions. All SFRs should be contained in the upper 128 bytes of bank 15, if possible. If the SFRs do not use all the available

locations on a particular device, the unused locations will be unimplemented and read as '0's. Certain devices, such as LCD controllers may have SFR areas in other banks than bank 15.

The boundary of the SFR's in bank 15 can be modified from device to device.  
5 At least 16 GPR's must be included in the Access Bank. Figure 43 displays a possible Special Function Register map. Figures 44 and 45 displays a summary of the core Special Function Registers.

#### Addressing Modes

10 There are 7 data addressing modes supported by the present invention:

- inherent
- literal
- direct short
- direct forced
- 15 • direct long
- indirect
- indexed indirect offset

Three of the modes, direct forced, direct long and indirect indexed, are new to the PIC  
20 architecture.

#### Inherent

Some instructions such as DAW do not require addressing other than that explicitly defined in the opcode.

#### Literal

25 Literal instructions contain a literal constant field, typically used in a mathematical operation such as ADDLW. Literal addressing is also used for GOTO, CALL, and branch opcodes.

#### Direct Short

Most mathematical and move instructions operate in the direct short addressing  
30 mode. In this addressing mode, the instruction contains eight bits of least significant address for the data. The remaining four bits of address are from the Bank Select

Register or BSR. The BSR is used to switch between banks in the data memory area (see Figure 47).

The need for a large general purpose memory space dictated a general purpose RAM banking scheme. The lower nibble of the BSR selects the currently active general purpose RAM bank. To assist this, a MOVLB bank instruction has been provided in the instruction set.

If the currently selected bank is not implemented (such as Bank 13), any read will read all '0's. Any write is completed to the bit bucket and the STATUS register bits will be set/cleared as appropriate.

#### 10                    Direct Forced

All the Special Function Registers (SFRs) are mapped into the data memory space. In order to allow easy access to the SFR's, they are all, generally, mapped in Bank 15. To simplify access, there is a 1 bit field in the instruction that points the address to the lower half of bank 0 for common RAM and the upper half of bank 15 for the SFR's regardless of the contents of the BSR. With the BSR set to BSR=n then, it is possible to address 3 banks with any instruction; Bank 0 and 15 in direct forced mode and Bank "n" in direct short mode.

#### Direct Long

The direct long addressing codes all twelve bits of the data address into the instruction. Only the MOVFF instruction uses this mode.

#### Indirect Addressing

Indirect addressing is a mode of addressing data memory where the data memory address in the instruction is determined by another register. This can be useful for data tables or stacks in the data memory. Figure 53 shows the operation of indirect addressing. The value of the FSR register is used as the data memory address.

#### Indirect Addressing Registers

The present invention has three 12-bit registers for indirect addressing. These registers are:

- FSR0H and FSR0L
- FSR1H and FSR1L
- FSR2H and FSR2L

The FSR's are 12-bit registers and allow addressing anywhere in the 4096-byte data memory address range.

In addition, there are registers INDF0, INDF1 and INDF2 which are not physically implemented. Reading or writing to these registers activates indirect addressing, with the value in the corresponding FSR register being the address of the data. If file INDF0 (or INDF1,2) itself is read indirectly via an FSR, all '0's are read (Zero bit is set). Similarly, if INDF0 (or INDF1,2) is written to indirectly, the operation will be equivalent to a NOP, and the STATUS bits are not affected.

#### Indirect Addressing Operation

Each INDF register has four addresses associated with it. When a data access is done to the one of the four INDF locations, the address selected will configure the FSR register to (see also Section 3.14.6.3 for indirect addressing with offset):

- Auto-decrement the value (address) in the FSR after an indirect access (post-decrement)
- Auto-increment the value (address) in the FSR after an indirect access (post-increment)
- Auto-increment the value (address) in the FSR before an indirect access (pre-increment)
- No change to the value (address) in the FSR after an indirect access (no change)

When using the auto-increment or auto-decrement features, the effect on the FSR is not reflected in the STATUS register. For example, if the indirect address causes the FSR to equal '0', the Z bit will not be set. Adding these features allows the FSR to be used as a stack pointer in addition to its uses for data table operations.

### Indexed Indirect Addressing

Each INDF has an address associated with it that performs an indexed indirect access. When a data access to this INDF location occurs, the FSR is configured to:

- 5       • Add the signed value in the W register and the value in FSR to form the address before an indirect access.
- The FSR value is not changed.

### Indirect Writing of Indirect Addressing (INDF) Registers

- 10       If an FSR register contains a value that points to one of the indirecting registers (FEFh-FEBh, FE7h-FE3h, FDFh-FDBh), an indirect read will read 00h (Zero bit is set) while an indirect write will be equivalent to a NOP (STATUS bits are not affected).

### Indirect Writing of Pointer (FSR) Registers

- 15       If an indirect addressing operation is done where the target address is an FSRnH or FSRnL register, the write operation will dominate over the pre or post increment/decrement functions. For example:

FSR0 = FE8h (one less than the location of FSR0L)

W=50h

MOVWF \*(++FSR0);(PREINC0)

- 20       will increment FSR0 by one to FE9h, pointing to FSR0L. Then write of W into FSR0L will change FSR0L to 50h. However,

FSR0 = FE9h (the location of FSR0L)

W = 50h

MOVWF \*FSR0++;(POSTINC0)

- 25       will attempt to write W into the FSR0L at the same time the increment of FSR0 is to occur. The write of W will prevail over the post increment and FSR0L will be 50h.

### Instruction Set Summary

The instruction set of the present invention consists of 77 instructions. Due to excessive page and bank switching in prior art architectures, the Program and Data

memory maps needed to be linearized, and the instruction set was modified to facilitate this linearization. The Data Memory space of the preferred embodiment of the present invention has a maximum of 4K bytes, which is made up of 16 banks of 256 bytes each. In the preferred embodiment of the present invention, with all Special Function  
5 Registers located in one bank, it is preferred to designate a bit in the opcode of all the instructions that perform file manipulation that could force a virtual bank. Therefore, it is not necessary to switch banks in order to access Special Function Registers.

The Program Memory space was modified over the prior art systems to be a maximum of 2M bytes in the preferred embodiment. The PC was increased from 13  
10 bits to up to 21 bits, and some instructions that cause a jump (CALL, GOTO) were changed to two-word instructions to load the 21-bit value for the PC. Another improvement over the prior art was the inclusion of a modular emulator. This requires communication between two chips for emulation, and to achieve the desired speeds, it is not possible to have different source and destination registers within the same  
15 instruction cycle. Therefore, the MOVPF and MOVFP instructions in the prior art were eliminated. To keep this functionality, a two-word instruction, MOVFF, was added.

The instruction set of the present invention can be grouped into three types:

- byte-oriented
- bit-oriented
- 20 • literal and control operations.

These formats are shown in Figure 56. Figure 54 shows the field descriptions for the opcodes.

These descriptions are useful for understanding the opcodes in Figures 57-59 and in  
25 each specific instruction description found in Appendix A. Figure 114 shows the instruction decode map.

For byte-oriented instructions, 'f' represents a file register designator and 'd' represents a destination designator. The file register designator specifies which file register is to be used by the instruction. The destination designator specifies where the

result of the operation is to be placed. If 'd' = '0', the result is placed in the W register. If 'd' = '1', the result is placed in the file register specified by the instruction.

Again, for byte-oriented instructions, 'a' represents the virtual bank select bit. If 'a' = '0', the BSR is overridden and virtual bank is selected. If 'a' = '1', the bank select register (BSR) is not overridden.

For bit-oriented instructions, 'b' represents a bit field designator which selects the number of the bit affected by the operation, while 'f' represents the address of the file in which the bit is located.

For literal and control operations, 'k' represents an 8-, 12-, 16- or 20-bit constant or literal value. Moreover, 's' represents the fast call/return select bit. If 's' = '0', the shadow registers are unused. If 's' = '1', the W, BSR and STATUS registers are updated from shadow registers on a RETURN or RETFIE instruction, or the shadow registers are loaded from their corresponding register on a CALL instruction. Finally, 'n' is a 2's complement number that determines the direction and magnitude of the jump for relative branch instructions.

The instruction set is highly orthogonal and is grouped into:

- byte-oriented operations
- bit-oriented operations
- literal and control operations

All instructions are executed within one single instruction cycle, unless:

- a conditional test is true
- the program counter is changed as a result of an instruction
- a file to file transfer is executed
- a table read or a table write instruction is executed

which in that case, the execution takes two instruction cycles with the second cycle executed as a NOP.

#### Special Function Registers as Source/Destination

The orthogonal instruction set of the present invention allows read and write of all file registers, including special function registers. There are some special situations the user should be aware of:

### STATUS as destination

If an instruction writes to the STATUS register, the Z, C, DC, OV and N bits may be set or cleared as a result of the instruction and overwrite the original data bits written.

5

### PCL as source or destination

Read, write or read-modify-write on PCL may have the following results:

- For a Read PCL, first PCU to PCLATU; then PCH to PCLATH; and then PCL to dest.
- For a Write PCL, first PCLATU to PCU; then PCLATH to PCH; and then 8-bit result value to PCL.
- For a Read-Modify-Write: first PCL to ALU operand, then PCLATH to PCH, then PCLATU to PCU, and then 8-bit result to the PCL.

10

Where:

PCL = program counter low byte

15

PCH = program counter high byte

PCLATH = program counter high holding latch

PCU = program counter upper byte

PCLATU = program counter upper holding latch

dest = destination, W or f.

20

### Bit Manipulation

All bit manipulation instructions are done by first reading the entire register, operating on the selected bit and writing the result back (read-modify-write (R-M-W)). The user should keep this in mind when operating on some special function registers, such as ports. It should be noted that the Status bits that are manipulated by the device (including the Interrupt flag bits) are set or cleared in the Q1 cycle. So there is no issue on doing R-M-W instructions on registers which contain these bits.

25

Figures 60-113 contain flowcharts for the general operation of each of the instructions within the instruction set of the present invention. The various Figures show generalized as well as specific steps for the fetching and the execution of the instructions within the instruction set of the present invention. For example, Figure 60 shows the steps for the fetching of byte oriented file register operations, which includes the instructions ADDWF, ADDWFC, ANDWF, COMF, DECF, INCF, IORWF, MOVF, RLCF, RLNCF, RRCF, RRNCF, SUBFWB, SUBWF, SUBWFB, SWAPF, XORWF, MOVWF, and NOP. Similarly, Figure 61 shows the steps for the execution of the byte oriented file register operations, which includes the instructions ADDWF, ADDWFC, ANDWF, COMF, DECF, INCF, IORWF, MOVF, RLCF, RLNCF, RRCF, RRNCF, SUBFWB, SUBWF, SUBWFB, SWAPF, and XORWF (but MOVWF does only a dummy read and NOP does a dummy read and a dummy write).

Figure 77 shows the fetch steps for the Literal Operations, which includes the instructions: ADDLW, ANDLW, IORLW, MOVLW, SUBLW, and XORLW. As before, Figure 78 shows the execution steps for the Literal Operations, which includes the instructions: ADDLW, ANDLW, IORLW, MOVLW, SUBLW, and XORLW.

Figure 90 shows a flow chart for the fetching of the Branch Operations, which includes the instructions: BC, BN, BNC, BNN, BNV, BNZ, BV, and BZ. Similarly, Figure 90 shows a flow chart for the execution of the Branch Operations, which includes the instructions: BC, BN, BNC, BNN, BNV, BNZ, BV, and BZ. The remaining figures show the steps of fetching and execution of the other instructions within the instruction set.

For those multi-Word instructions that require two fetches to obtain the complete instruction, three flowcharts are used to describe the entire fetch and execute process. For example, the MOVFF instruction is described in Figures 70-72. Figure 70 shows a relatively standard fetch operation. However, Figure 71 shows the execution of the first portion of the MOVFF in the left side of the operation boxes while the right portion of the

operation boxes show the fetching of the second Word of the instruction. Correspondingly, Figure 72 shows simply the execution steps of the second Word of the MOVFF instruction. Similar flow charts are provided for the other multi-Word instructions: LFSR (Figures 79-81); GOTO (Figures 102-104); CALL (Figures 105-107),  
5 TBLRD\*, TBLRD\*+, TBLRD\*-, and TBLRD+\* (Figures 108-110); TBLWT\*,  
TBLWT\*+, TBLWT\*-, and TBLWT+\* (Figures 111-113).

Appendix A contains a detailed listing of the opcodes and instructions of the instruction set of the present invention. The material in Appendix A is incorporated herein by reference for all purposes.

10 The present invention, therefore, is well adapted to carry out the objects and attain the ends and advantages mentioned, as well as others inherent therein. While the present invention has been depicted, described, and is defined by reference to particular preferred embodiments of the invention, such references do not imply a limitation on the invention, and no such limitation is to be inferred. The invention is capable of  
15 considerable modification, alternation, and equivalents in form and function, as will occur to those ordinarily skilled in the pertinent arts. The depicted and described preferred embodiments of the invention are exemplary only, and are not exhaustive of the scope of the invention. Consequently, the invention is intended to be limited only by the spirit and scope of the appended claims, giving full cognizance to equivalents in  
20 all respects.

CLAIMS

1. A microcontroller comprising:
  - a central processing unit;
  - a linearized address space in operative relationship with said central
  - 5 processing unit, said linearized address space capable of direct addressing mode or indirect addressing mode through a data memory;
  - a program counter register within said central processing unit, said program counter mapped in said data memory;
  - a working register within said central processing unit, said working
  - 10 register mapped in said data memory; and
  - an orthogonal instruction set stored in a program memory, said instruction set constructed and arranged to designate at least one operation of said microcontroller;
  - wherein said microcontroller is capable of any of said operations
  - 15 on any of said registers using any of said addressing modes.
2. A microcontroller comprising:
  - a central processing unit;
  - a linearized address space in operative relationship with said
  - central processing unit, said linearized address space capable of direct addressing mode or
  - 20 indirect addressing mode through a register file;
  - a program counter register within said central processing unit, said program counter mapped in said register file;
  - a working register within said central processing unit, said working register mapped in said register file; and
  - 25 an orthogonal instruction set stored in a program memory, said instruction set constructed and arranged to designate at least one operation of said microcontroller;
  - wherein said microcontroller is capable of any of said operations on any of said registers using any of said addressing modes.

3. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 1111 kkkk kkkk, wherein the contents of a 'W' register are added to an 8-bit literal 'k' and the result is placed in said 'W' register, said literal 'k' is designated in said kkkk kkkk portion of said instruction.

5 4. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0010 01da ffff ffff, wherein the contents of a 'W' register are added to an 'f' register, a location for said 'f' register is designated by said ffff ffff portion of said instruction, said 'd' portion of said instruction designates a location to which a result of said instruction is sent, said 'a' bit of said instruction affects  
10 which of a plurality of memory banks is selected.

5. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0010 00da ffff ffff, wherein the contents of a 'W' register are added both to a Carry Flag and to the contents of an 'f' register, a location for said 'f' register is designated by said ffff ffff portion of said instruction, said 'd'  
15 portion of said instruction designates a location to which a result of said instruction is sent, said 'a' bit of said instruction affects which of a plurality of memory banks is selected..

6. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 1011 kkkk kkkk, wherein the contents of a 'W' register are AND'ed with an 8-bit literal 'k' designated by said kkkk kkkk portion of  
20 said instruction, a result of said instruction is placed in said 'W' register.

7. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0010 01da ffff ffff, wherein the contents of a 'W' register are AND'ed with the contents of an 'f' register, a location for said 'f' register is designated by said ffff ffff portion of said instruction, said 'd' portion of said instruction  
25 designates a location to which a result of said instruction is sent, said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

8. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1110 0010 nnnn nnnn, wherein if a Carry bit is set to '1'

then a program written with said instruction set will branch to a location designated in said nnnn nnnn portion of said instruction.

9. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1001 bbba ffff ffff, wherein wherein a bit 'b' in a register 'f' is cleared, said bit 'b' is designated by said bbb portion of said instruction, a location for said 'f' register is designated by said ffff ffff portion of said instruction, said 'a' bit of said instruction affects which of a plurality of memory banks is selected. 10.

- A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1110 0110 nnnn nnnn, wherein if a negative bit is set to 1, then a program composed from said instructions of said instruction set will branch to a location designated by said nnnn nnnn portion of said instruction.

11. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1110 0011 nnnn nnnn, wherein if a Carry bit is set to 0, then a program composed from said instruction set will branch to a location designated by said nnnn nnnn portion of said instruction.

12. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1110 0111 nnnn nnnn, wherein if a Negative bit is set to 0, then a program composed from said instruction set will branch to a location designated by said nnnn nnnn portion of said instruction.

13. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1110 0101 nnnn nnnn, wherein if an Overflow bit is set to 0, then a program composed from said instruction set will branch to a location designated by said nnnn nnnn portion of said instruction.

14. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1110 0001 nnnn nnnn, wherein if a Zero bit is set to 0, then a program composed from said instruction set will branch to a location designated by said nnnn nnnn portion of said instruction.

15. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1101 0nnn nnnn nnnn, wherein a program composed

from said instruction set will branch to a location designed in said nnn nnnn nnnn portion of said instruction.

16. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1000 bbba ffff ffff, wherein a bit 'b' in a register 'f' is set, the location of said register 'f' is designated by said ffff ffff portion of said instruction, said bit 'b' is designated by said bbb portion of said instruction, said 'a' bit of said instruction is used to designate a memory bank.

17. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1011 bbba ffff ffff, wherein if a bit 'b' in register 'f' is set to 0, then the next instruction in a program composed from said instruction set is skipped, said bit 'b' is designated in said bbb portion of said instruction, a location of said 'f' register is designated in said ffff ffff portion of said instruction, and said 'a' bit of said instruction designates a memory bank.

18. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1010 bbba ffff ffff, wherein if a bit 'b' in a register 'f' is set to 1, then the next instruction of a program composed from said instruction set is skipped, said bit 'b' is designated in said bbb portion of said instruction, a location for said register 'f' is designated in said ffff ffff portion of said instruction, said 'a' bit in said instruction is used to designated a memory bank.

19. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0111 bbba ffff ffff, wherein a bit 'b' in a data memory location 'f' is inverted, said memory location 'f' is designated by said ffff ffff portion of said instruction, said bit 'b' is designated by said bbb portion of said instruction, and said 'a' bit of said instruction designates a memory bank.

20. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1110 0100 nnnn nnnn, wherein if an Overflow bit is set to 1, then a program composed from said instruction set will branch to a location designated by said nnnn nnnn portion of said instruction.

21. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1110 0000 nnnn nnnn, wherein if a Zero bit is set to 1, then a program composed from said instruction set will branch to a location designated by said nnnn nnnn portion of said instruction.

5 22. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1110 110s kkkk kkkk 1111 kkkk kkkk kkkk, wherein said instruction is a subroutine call of an entire 2 mega byte memory range, said 's' bit of said instruction is used to modify the behavior of said instruction, said memory range designated by said kkkk kkkk kkkk portions of said instruction.

10 23. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0110 101a ffff ffff, wherein said instruction clears the content of the specified register designated by said ffff ffff portion of said instruction, said 'a' bit of said instruction is used to modify the behavior of said instruction.

15 24. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 0000 0000 0100, wherein said instruction resets a Watchdog Timer.

25. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0001 11da ffff ffff, wherein the contents of a register 'f' are complemented, said register 'f' designated by said ffff ffff portion of said instruction, said 'd' bit of said instruction designates whether a result of said instruction is stored back in said register 'f', said 'a' bit of said instruction is used to designate a memory bank. 26. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0110 001a ffff ffff, wherein the contents of a data memory location 'f' designated in said ffff ffff portion of said instruction is compared to the contents of a 'W' register, said 'a' bit of said instruction is used to designate a memory bank.

20 25

27. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0110 010a ffff ffff, wherein the contents of a data memory location 'f' designated by said ffff ffff portion of said memory are compared to

the contents of a 'W' register, said 'a' bit of said instruction is used to designate a memory bank.

28. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0110 000a ffff ffff, wherein the contents of a data  
5 memory location 'f' are compared to the contents of a 'W' register, said 'a' bit of said instruction used to designate a memory bank, said ffff ffff portion of said instruction used to designate an address for said data memory location 'f'.

29. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 0000 0000 0111, wherein said instruction adjusts  
10 an eight bit value in a 'W' register to produce a correctly packed BCD result.

30. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0100 11da ffff ffff, wherein the contents of a register 'f'  
are decremented, a data memory location for said register 'f' is designated by said ffff  
ffff portion of said instruction, said 'd' bit of said instruction determines the placement  
15 of a result of said instruction, said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

31. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 01da ffff ffff, wherein the contents of a register 'f'  
are decremented, said ffff ffff portion of said instruction designate a location for said  
20 register 'f', said 'd' bit of said instruction indicates if a result of said instruction is stored in said register 'f', said 'a' bit of said instruction indicates how a memory bank is selected.

32. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0010 11da ffff ffff, wherein the contents of an 'f'  
25 register are decremented, said 'd' bit of instruction directs whether a result of said instruction is placed within a 'W' register, said 'a' bit of said instruction affects which of a plurality of memory banks is selected, said ffff ffff portion of said instruction designating a memory location in said memory bank.

33. A microcontroller as in claim 1 wherein said instruction set includes an

instruction with an encoding of 1110 1111 kkkk kkkk 1111 kkkk kkkk kkkk, wherein wherein said instruction provides an unconditional branch for a program composed from said instruction set anywhere within a 2 megabyte memory range designated by said kkkk kkkk kkkk portions of said instruction.

5           34. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 0000 0000 0001, wherein the execution of a program composed from said instruction set is halted.

          35. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0010 10da ffff ffff, wherein the contents of a register 'f'  
10 are incremented, a data memory location for said register 'f' is designated by said ffff ffff portion of said instruction, said 'd' bit of said instruction determines the placement of a result of said instruction, said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

          36. A microcontroller as in claim 1 wherein said instruction set includes an  
15 instruction with an encoding of 0011 11da ffff ffff, wherein the contents of a register 'f' are incremented, a data memory location for said register 'f' is designated by said ffff ffff portion of said instruction, said 'd' bit of said instruction determines the placement of a result of said instruction, said 'a' bit of said instruction affects which of a plurality of memory banks is selected, if said result of said instruction is 0, then the next  
20 instruction of a program composed from said instruction set will be discarded and a NOP instruction will be executed in place of said discarded instruction.

          37. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0100 10da ffff ffff, wherein the contents of a register 'f' are incremented, a data memory location for said register 'f' is designated by said ffff  
25 ffff portion of said instruction, if said 'd' bit of said instruction is set to 1 then a result of said instruction is placed in said 'f' register, said 'a' bit of said instruction affects which of a plurality of memory banks is selected, if said result of said instruction is 0, then the next instruction of a program composed from said instruction set will be discarded and a NOP instruction will be executed in place of said discarded instruction.

38. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 1001 kkkk kkkk, wherein the contents of a 'W' register are OR'ed with an eight bit literal 'k', the location of said eight bit literal 'k' is designated in said kkkk kkkk portion of said instruction.

5 39. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0001 00da ffff ffff, wherein said instruction performs an inclusive OR with a 'W' register and an 'f' register, a data memory location for said 'f' register is designated by said ffff ffff portion of said instruction, if said 'd' bit of said instruction is set to 0 then a result of said instruction is placed back in said 'f' register,  
10 said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

40. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1110 1110 00ff kkkk 1111 0000 kkkk kkkk, wherein a 12-bit literal 'k' is loaded into a file select register pointed to by said ff portion of said instruction, said 12-bit literal 'k' is encoded within said kkkk kkkk kkkk portion of said  
15 instruction.

41. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0101 00da ffff ffff, wherein the contents of a register 'f' are moved to a destination dependent upon a status of said 'd' bit of said instruction, if said 'd' bit is set to 0 then a result of said instruction is placed into a 'W' register, if said  
20 'd' bit is set to 1 then said result is placed back in said register 'f', said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

42. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1100 ffff ffff ffff 1111 gggg gggg gggg, wherein the contents of a source register 'f' are moved to a destination register 'g', a location of said  
25 source register 'f' can be anywhere in a 4096 byte data space and a location of said destination register 'g' can be anywhere within said data space.

43. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 0001 kkkk kkkk, wherein an 8-bit literal 'k' is loaded into a Bank Select Register (BSR), said 8-bit literal 'k' is encoded within said

kkkk kkkk portion of said instruction.

44. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 1110 kkkk kkkk, wherein an eight bit literal 'k' is loaded into a 'W' register, said eight bit literal 'k' is encoded within said kkkk kkkk  
5 portion of said instruction.

45. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 1101 kkkk kkkk, wherein said instruction implements an unsigned multiplication between the contents of a 'W' register and an 8-bit literal 'k', an address for said literal 'k' is contained within said kkkk kkkk portion of  
10 said instruction.

46. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 001a ffff ffff, wherein said instruction implements an unsigned multiplication between the contents of a 'W' register and a register file location 'f', said address of said file location 'f' is contained within said ffff ffff portion  
15 of said instruction, said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

47. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0110 110a ffff ffff, wherein said instruction negates the contents of an 'f' register whose address is designated by said ffff ffff portion of said  
20 instruction, said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

48. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 0000 0000 0000 1111 xxxx xxxx xxxx, wherein said instruction performs no operation, and the contents of said xxxx xxxx xxxx portion  
25 of said instruction are ignored.

49. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 0000 0000 0110, wherein a top of stack (TOS) values is pulled of of a return stack and is discarded.

50. A microcontroller as in claim 1 wherein said instruction set includes an

instruction with an encoding of 0000 0000 0000 0101, wherein a value equivalent to a program counter register plus two is pushed onto a top of a return stack.

51. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 1101 1nnn nnnn nnnn, wherein said instruction  
5 implements a subroutine call to a subroutine that is up to 1K from a current location within a program composed from said instruction set, said nnn nnnn nnnn portion of said instruction designates an address to said subroutine.

52. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 0000 1111 1111, wherein said instruction  
10 provides a way to execute a MCLR reset in software.

53. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 0000 0001 000s, wherein said instruction returns from an interrupt, said 's' portion of said instruction manipulates the contents of a shadow register.

15 54. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0011 01da ffff ffff, wherein the contents of an 'f' register are rotated one bit to the left through a Carry flag, a location for said 'f' register is designated by said ffff ffff portion of said instruction, said 'd' portion of said instruction designates a location to which a result of said instruction is sent, said 'a' bit  
20 of said instruction affects which of a plurality of memory banks is selected.

55. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0100 01da ffff ffff, wherein the contents of an 'f' register are rotated one bit to the left, a location for said 'f' register is designated by said ffff ffff portion of said instruction, said 'd' portion of said instruction designates a  
25 location to which a result of said instruction is sent, said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

56. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0011 00da ffff ffff, wherein the contents of an 'f' register are rotated one bit to the right thorough a Carry flag, a location for said 'f'

register is designated by said ffff ffff portion of said instruction, said 'd' portion of said instruction designates a location to which a result of said instruction is sent, said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

57. A microcontroller as in claim 1 wherein said instruction set includes an  
5 instruction with an encoding of 0100 00da ffff ffff, wherein the contents of an 'f' register are rotated one bit to the right, a location for said 'f' register is designated by said ffff ffff portion of said instruction, said 'd' portion of said instruction designates a location to which a result of said instruction is sent, said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

10 58. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0110 100a ffff ffff, wherein the contents of an 'f' register are set to FFh, a location for said 'f' register is designated by said ffff ffff portion of said instruction, said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

15 59. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 0000 0000 0011, wherein a power-down status bit is cleared, a time-out status bit is set, and a Watchdog Timer and a postscaler are cleared.

20 60. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0101 01da ffff ffff, wherein the sum of an 'f' register and a carry flag are subtracted from a 'W' register, a location for said 'f' register is designated by said ffff ffff portion of said instruction, said 'd' portion of said instruction designates a location to which a result of said instruction is sent, said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

25 61. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 1000 kkkk kkkk, wherein the contents of a 'W' register are subtracted from an eight bit literal 'k' and a result of said instruction is placed in said 'W' register, a location for said literal 'k' is contained within said kkkk kkkk portion of said instruction.

62. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0101 11da ffff ffff, wherein the contents of a 'W' register are subtracted from an 'f' register, a location for said 'f' register is designated by said ffff ffff portion of said instruction, said 'd' portion of said instruction designates a location to which a result of said instruction is sent, said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

63. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0101 10da ffff ffff, wherein the sum of the contents of a 'W' register and a carry flag are subtracted from an 'f' register, a location for said 'f' register is designated by said ffff ffff portion of said instruction, said 'd' portion of said instruction designates a location to which a result of said instruction is sent, said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

64. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0011 10da ffff ffff, wherein an upper nibble of an 'f' register is exchanged with a lower nibble of said 'f' register, a location for said 'f' register is designated by said ffff ffff portion of said instruction, said 'd' portion of said instruction designates a location to which a result of said instruction is sent, said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

65. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 0000 0000 10nn, wherein said nn portion of said instruction is a member selected from the group consisting of 00, 01, 10, or 11 that corresponds to a disposition of no change, post-increment, post-decrement, and pre-increment, respectively; said nn portion of said instruction used to determine the disposition of a 21-bit table pointer, the contents of a program memory location pointed to by said table pointer are loaded into an 8-bit table latch.

66. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 0000 0000 11nn, wherein said nn portion of said instruction is a member selected from the group consisting of 00, 01, 10, or 11 that corresponds to a disposition of no change, post-increment, post-decrement, and pre-

increment, respectively; said nn portion of said instruction used to determine the disposition of a 21-bit table pointer, the contents of a table latch are written to a program memory location pointed to by said table pointer.

67. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 0000 1110 0000, wherein said instruction is a debugger trap to 00028h.

68. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 0000 1110 0001, wherein said instruction is a return from a debugger trap.

69. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0110 011a ffff ffff, wherein the contents of an 'f' register is checked to determine if its value is equal to 0, a location of said 'f' register being designated by said ffff ffff portion of said instruction, if said value of 'f' register is equal to 0, then a next instruction is discarded and a NOP instruction is executed, said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

70. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0000 1010 kkkk kkkk, wherein the contents of a 'W' register are XOR'ed with an 8-bit literal 'k' and a result of said instruction is placed into said 'W' register, a location for said literal 'k' is designated in said kkkk kkkk portion of said instruction.

71. A microcontroller as in claim 1 wherein said instruction set includes an instruction with an encoding of 0001 10da ffff ffff, wherein the contents of a 'W' register are XOR'ed with the contents of an 'f' register, a location for said 'f' register is designated by said ffff ffff portion of said instruction, said 'd' portion of said instruction designates a location to which a result of said instruction is sent, said 'a' bit of said instruction affects which of a plurality of memory banks is selected.

12/95

When a device is reset, the PC is loaded with the reset vector (0h). The stack pointer is initialized to 00h, and the Top of Stack register (TOS) is 000000h.

Reset  
Fig. 22

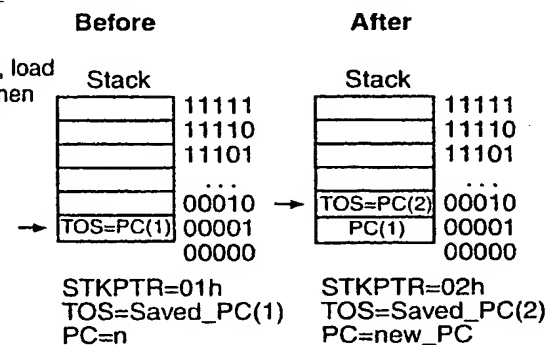

The first push of the stack increments the stack pointer to point to the location 1. The value in the PC is loaded into stack level 1. The PC is then updated.

First CALL on an initialized stack

Fig. 23

The second push will increment the stack pointer, load the TOS register with the current PC value, and then update the PC.

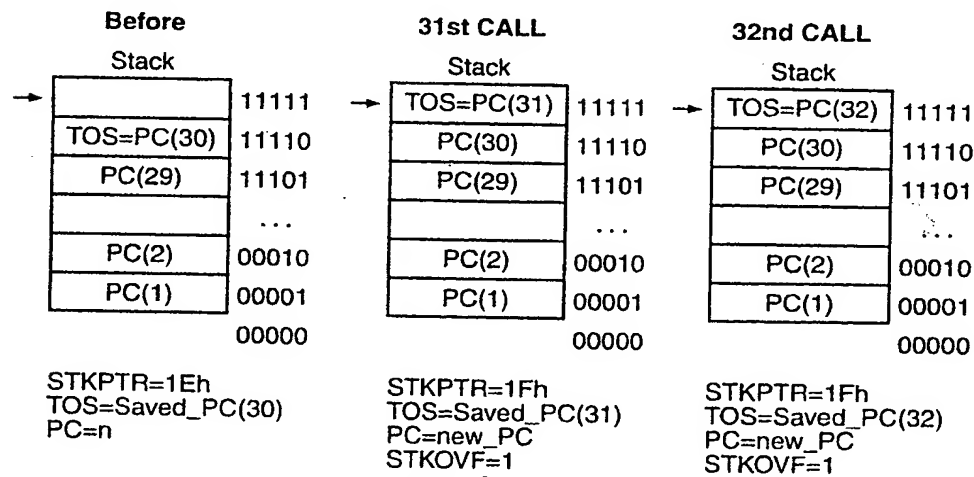

Second Consecutive CALL

Fig. 24

13/95

The 31st CALL will increment the stack pointer, load the TOS register with the current PC value, and then update the PC. The STKOVF bit is set to indicate the impending stack overflow.

The 32nd CALL will attempt to increment the stack pointer. However the stack pointer is now pointing at the upper most stack level and cannot be incremented. The pointer will be loaded with 1Fh (still pointing to stack level 31), and the TOS will be overwritten with the current PC value. The PC will be updated. The stack overflow bit remains set. Another push will yield the same results. Once the pointer had incremented to 1Fh, it cannot be incremented to a higher value, it can only be cleared or decremented.

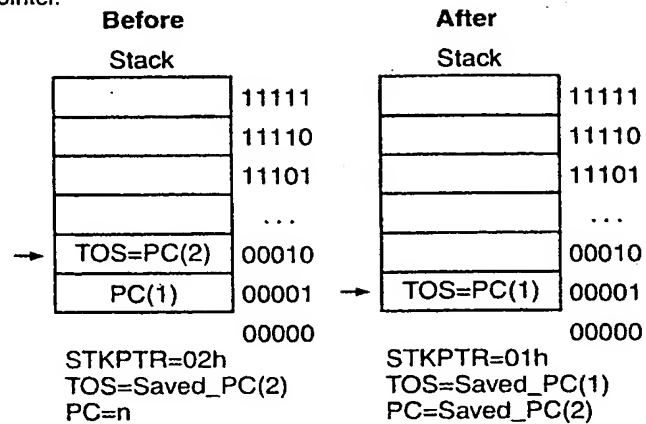

31st and 32nd consecutive CALL

Fig. 25

14/95

A return pop will copy the contents of the TOS to the PC and then decrement the stack pointer.

Return Pop

Fig. 26

When the stack has been popped enough to reach 00h and the stack pointer can no longer be decremented, further popping will return 000000h to the PC. The stack pointer will maintain the value of 00h. The underflow bit (STKUNF) is set.

Stack Return Pops Causing Stack Underflow

Fig. 27

SUBSTITUTE SHEET (RULE 26)

15/95

A PUSH instruction performs a similar operation as a call. The PC is incremented to PC+2, the stack pointer is incremented and the TOS is loaded with the PC value (which is essentially a wasted operation). The user will then have to access to write values into the TOS registers.

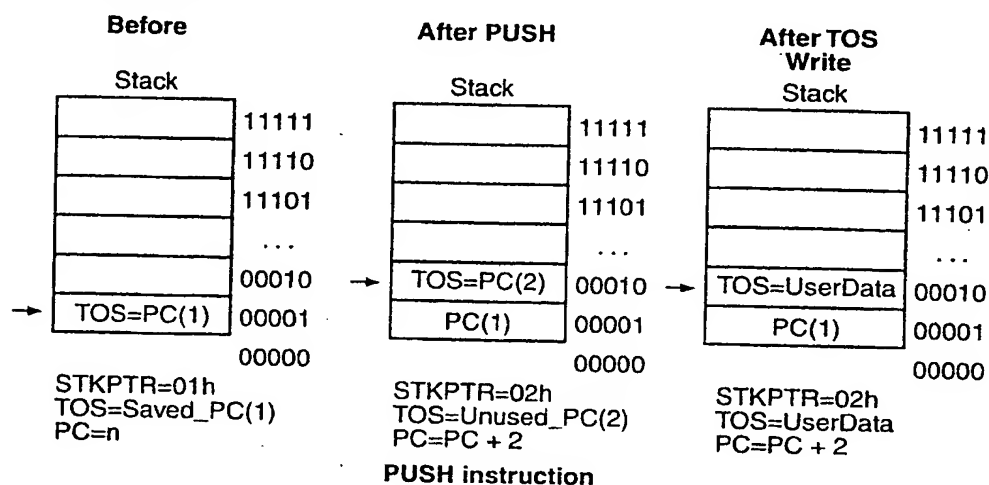

Fig. 28

The POP instruction will perform actions similar to a return, however the PC is not loaded with the TOS value. The user must recover his data before the POP. The stack pointer is then decremented.

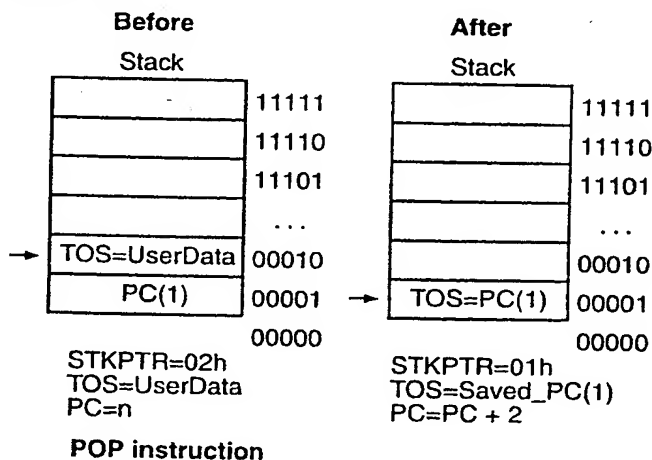

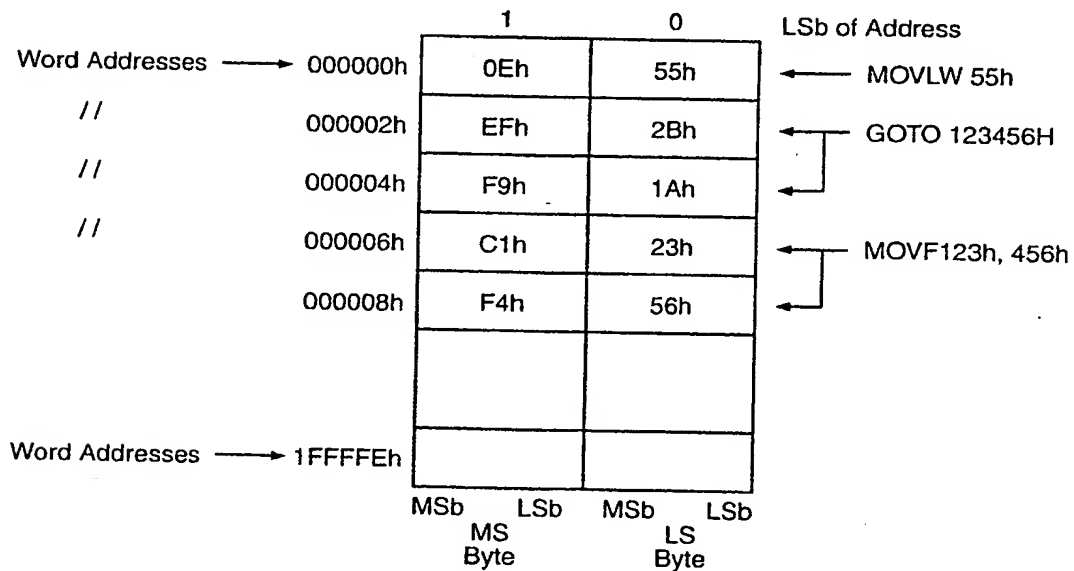

Fig. 29

Note 1:  
User memory space may be internal, external, or both. The memory configuration depends on the processor mode.

36/95

Field	Description
f fs fd	Register file address (00h to FFh) in current or virtual bank, except MOVFF (000h to FFFh)
a	Virtual bank select 0 = override BSR and force virtual bank 1 = do not override BSR Default is a = '1'
s	Fast call/return select 0 = do not update into/from shadow registers 1 = certain registers loaded into/from shadow registers Default is s = '0'
w	Working register (accumulator)
b	Bit address within an 8-bit file register
k	Literal field, constant data or label
n	2's complement number for relative branch instructions
x	Don't care location (= '0' or '1') The assembler will generate code with x = '0'. It is the recommended form of use for compatibility with all Microchip software tools.
d	Destination select 0 = store result in W 1 = store result in file register f Default is d = '1'
u	Unused, encoded as '0'
label	Label name
C, DC, Z, OV, N	ALU status bits Carry, Digit Carry, Zero, Overflow, Negative
GIE/ GIEH	Global Interrupt Enable bit (INTCON<7>)
PEIE/ GIEL	Low Priority Interrupt Enable bit (INTCON<6>)
TBLPTRU TBLPTRH TBLPTRL	Table Pointer (21-bit)
TABLAT	Table Latch (8-bit)
PRODL	Product of Multiply low byte
PRODH	Product of Multiply high byte
TOSU TOSH TOSL	Top of Stack

Field	Description
PCU PCH PCL	Program Counter
BSR	Bank Select Register
WDT	Watchdog Timer Counter
TO	Time-out bit
PD	Power-down bit
dest	Destination either the W register or the specified register file location
*	No Change to TBLPTR
*+	Post-Increment TBLPTR
*-	Post-Decrement TBLPTR
++	Pre-Increment TBLPTR
[ ]	Options
( )	Contents
→	Assigned to
<>	Register bit field

Opcode Field Descriptions

Fig. 54

Field	Description
*FSRn	Selects INDFn Register
*FSRn++	Selects POSTINCn Register
*FSRn--	Selects POSTDECn Register
*(++FSRn)	Selects PREINCn Register
*(FSRn+W)	Selects PLUSWn Register

Indirect Addressing Symbols

Fig. 55

Figures 54 and 55 lists the symbols recognized by the MPASM assembler

Note 1: Any unused opcode is Reserved. Use of any reserved opcode may cause unexpected operation.

All instruction examples use the following format to represent a hexadecimal number:

0xnn

where 0x signifies a hexadecimal digit.

To represent a binary number:

nnnnnnnnb

where b signifies a binary string.

**37/95****Byte-oriented file register operations**

15	10	9	8	7	0
OPCODE			d	a	f (FILE #)

d = 0 for destination W  
 d = 1 for destination f  
 a = 0 for force Virtual bank  
 a = 1 for BSR to select bank  
 f = 8-bit file register address

**Byte to Byte move operations (2-word)**

15	12	11	0
OPCODE		f (Source FILE #)	

15	12	11	0
1111		f (Destination FILE #)	

f = 12-bit file register address

**Bit-oriented file register operations**

15	12	11	9	8	7	0
OPCODE			b (BIT #)	a	f (FILE #)	

b = 3-bit address  
 a = 0 for force Virtual bank  
 a = 1 for BSR to select bank  
 f = 8-bit file register address

**Literal and control operations**

15	8	7	0
OPCODE		k (literal)	

k = 8-bit immediate value

**CALL and GOTO operations**

15	8	7	0
OPCODE			k<7:0> (literal)

15	12	11	0
1111		k<19:8> (literal)	

k = 20-bit immediate value

**General Format for Instructions****Fig. 56**

## 38/95

INCF f,d,a	Increment f	1	0010 10da	ffff ffff	C,DC,N,OV,Z	3
INCFSZ f,d,a	Increment f, skip if 0	1 (2)	0011 11da	ffff ffff	None	3,5,7,8
INFSNZ f,d,a	Increment f, skip if not 0	1 (2)	0100 10da	ffff ffff	None	3,5,7,8
IORWF f,d,a	Inclusive OR W with f	1	0001 00da	ffff ffff	N,Z	3
MOVF f,d,a	Move f	1	0001 00da	ffff ffff	N,Z	3
MOVFF fs,fd	Move fs (1st word) to fd (2nd word)	2	1100 ffff 1111 ffff	ffff ffff ffff ffff	None	6
MOVWF f,a	Move W to f	1	0110 111a	ffff ffff	None	3
MULWF f,a	Multiply W with f	1	0000 001a	ffff ffff	None	3
NEGF f,a	Negate f	1	0110 110a	ffff ffff	C,DC,N,OV,Z	1,3
NOP ---	No Operation	1	0000 0000	0000 0000	None	
NOP ---	No Operation (2nd Word)	1	1111 xxxx	xxxx xxxx	None	
RLCF f,d,a	Rotate left f though Carry	1	0011 01da	ffff ffff	C,N,Z	3
RLNCF f,d,a	Rotate left f (no carry)	1	0100 01da	ffff ffff	N,Z	3
RRCF f,d,a	Rotate right f through Carry	1	0011 00da	ffff ffff	C,N,Z	3
RRNCF f,d,a	Rotate right f (no carry)	1	0100 00da	ffff ffff	N,Z	3
SETF f,a	Set f	1	0110 100a	ffff ffff	None	3

Legend: Refer to Table 3-6 for opcode field descriptions.

Note 1: 2's Complement method.

- 2: Unsigned arithmetic.
- 3: If a = '0', the Bank Select Register (BSR) will be overridden and Virtual bank is selected; If a = '1', the BSR is used.
- 4: Multiple cycle instruction for EPROM programming when table pointer selects internal EPROM. The instruction is terminated by an interrupt event. Writing to external program memory is a two-cycle instruction.
- 5: Two-cycle instruction when condition is true, else single cycle instruction.
- 6: Two-cycle instruction except for MOVFF to PCL (program counter low byte) in which case it takes 3 cycles.
- 7: A "skip" means that the instruction fetched during execution of the current instruction is not executed, instead an NOP is executed.
- 8: When a "skip" instruction executes a skip and is followed by a 2-word instruction, 3 cycles will be executed.
- 9: If s = '1', certain registers will be loaded from/into shadow registers. If s = '0' no update occurs.

SUBSTITUTE SHEET (RULE 26)

# INTERNATIONAL SEARCH REPORT

International Application No  
PCT/US 00/07656

A. CLASSIFICATION OF SUBJECT MATTER  
IPC 7 G06F9/30 G06F9/34

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)  
IPC 7 G06F

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EP0-Internal

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	<p>WO 93 10501 A (MICROCHIP TECH INC) 27 May 1993 (1993-05-27)</p> <p>page 7, paragraph 1 page 12, line 3 -page 21, line 25 --- -/--</p>	<p>1-7, 15-19, 23-33, 35-40, 42-48, 50, 51, 54-57, 59-64, 69-71</p>

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

### Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance  
"E" earlier document but published on or after the international filing date  
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)  
"O" document referring to an oral disclosure, use, exhibition or other means  
"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention  
"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone  
"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.  
"&" document member of the same patent family

Date of the actual completion of the international search

17 July 2000

Date of mailing of the international search report

25/07/2000
